**FACULTY MENTOR DEPARTMENT:**

Department of Emergency Medicine

**RESEARCH PROJECT DESCRIPTION:**

Rapid sequence intubation (RSI) is an often lifesaving intervention in unstable patients presenting to the emergency department. However, the medications used during RSI, as well as the abrupt changes in respiratory physiology inherent in the procedure, can precipitate serious complications including hypotension, aspiration, and cardiac arrest. Despite the frequency with which this procedure is performed, thorough investigation of the incidence and long-term effects of such complications is lacking. Knowledge of the incidence of adverse outcomes associated with RSI and risk factors for these outcomes could improve the care of critically ill patients. Outcomes assessed will include presence and duration of peri-intubation hypotension, need for pressor support, cardiac dysrhythmias, length of mechanical ventilation, ICU and hospital stay, aspiration, adrenal insufficiency, and mortality.

The medical student will review emergency department and inpatient medical records and analyze the resulting data to identify complications, the outcomes of these complications, and factors associated with their development. The student will also participate in abstract preparation and presentation. Funding will be from internal sources.
